Per- and Polyfluoroalkyl Substances (PFAS)

- Per- and poly-fluoroalkylated substances (PFAS) are a class of chemicals that are ubiquitously found in the environment due to their wide use, persistence and high mobility.
- PFAS can contaminate drinking water and soil in proximity to locations where fire-fighting foams are used including fire fighting training areas at airports and military bases.
- There is a growing body of knowledge on PFOS and PFOA toxicity; however, little is known about the many other PFAS

Exposure and Regulation in Canada

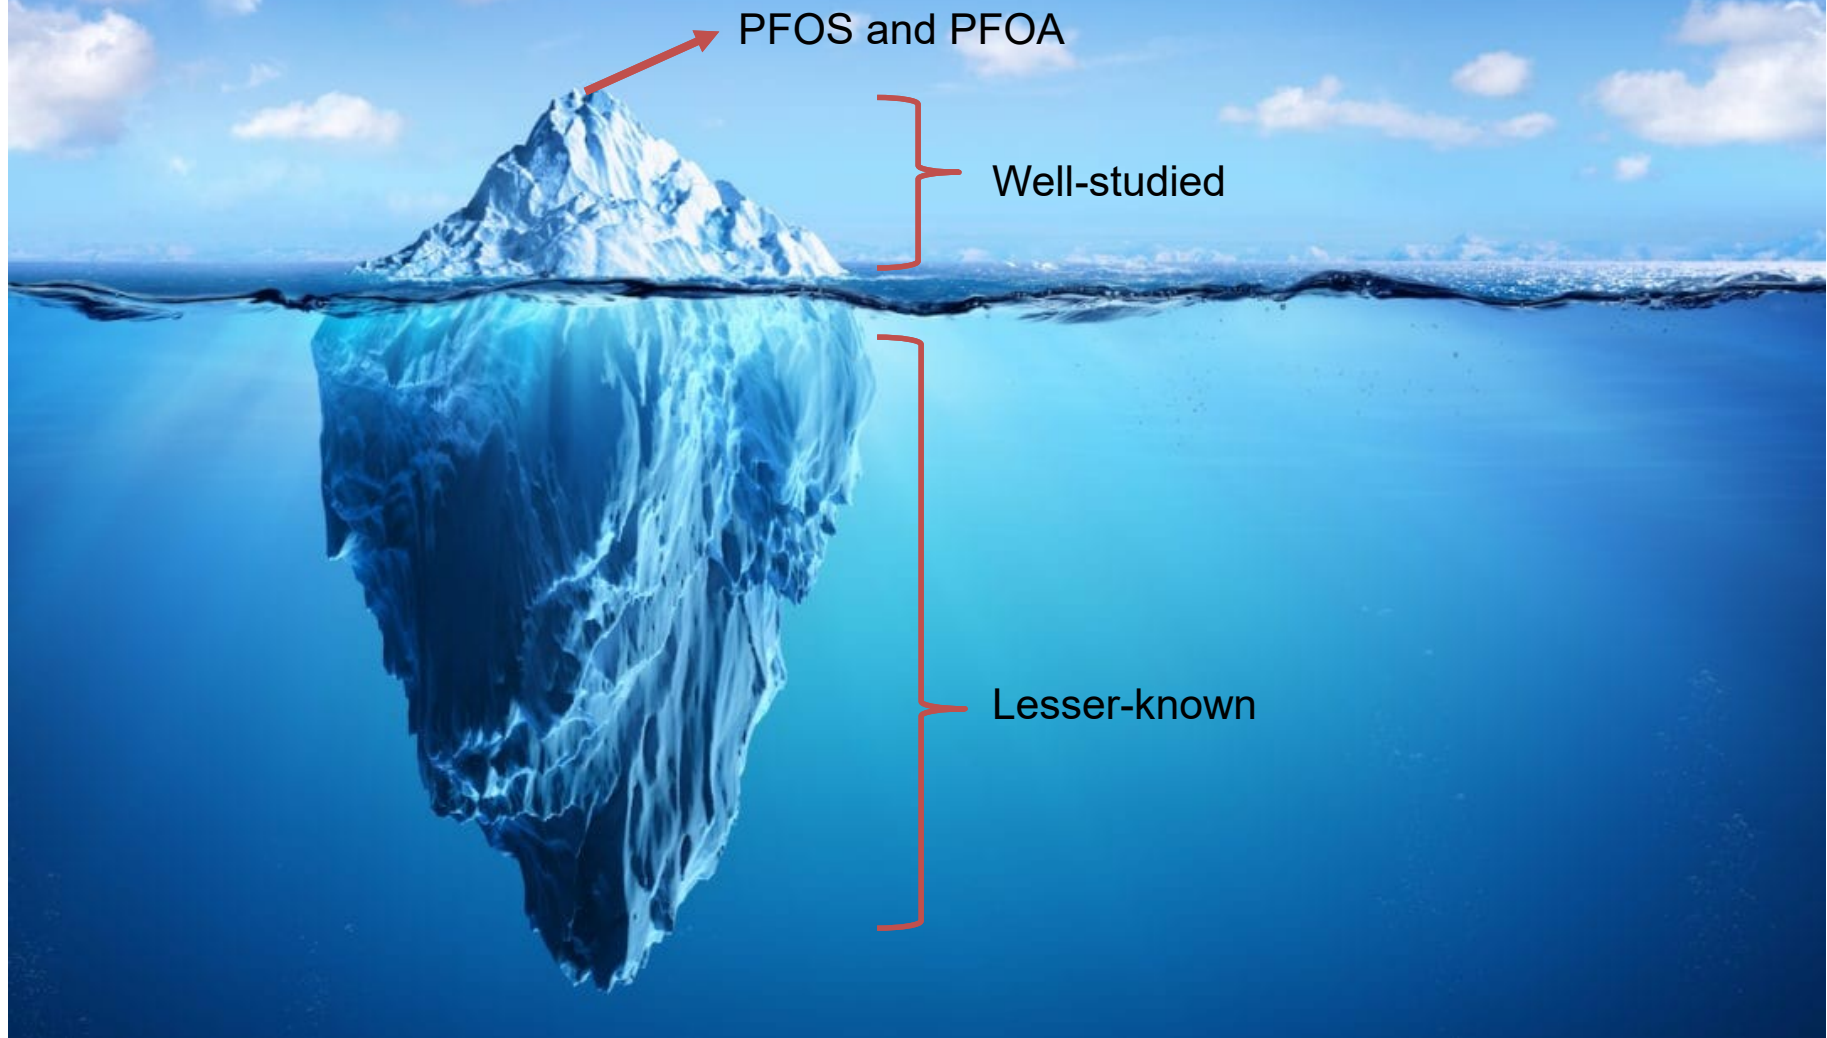

- Chemical persistence and broad use have led to wide-spread human exposure
- **Drinking water screening values** have been developed for PFOS, PFOA and 9 additional PFAS at the request of several provinces
- In 2018, **drinking water guidelines** were published for PFOS and PFOA, and screening values were updated
- **Soil Quality Guidelines** for PFOS and PFOA are currently being developed. **Soil screening values** are currently available for 9 PFAS compounds (including PFOS and PFOA).

2018 https://www.canada.ca/en/health-canada/services/environmental-workplace-health/reports-publications/water-quality.html#tech_doc

Scratching the Surface

Scratching the Surface

Thousands of PFAS!

The Challenge

- Gathering data on lesser-known chemicals
- Current approaches in toxicology cannot address all of these chemicals

**New Approach Methodologies
(NAMs)**

New Approach Methodologies

- The term new approach methodologies (NAMs) has been adopted as a broadly descriptive reference to any non-animal technology, methodology, approach, or combination thereof that can be used to provide information on chemical hazard and risk assessment.” (NIEHS roadmap, 2017)
- US EPA directive to reduce (by 2025) and subsequently eliminate (by 2035) the use of animal models in toxicological assessment

Long-term vision of transcriptomics in regulatory decision making

Extract predictive signatures and pathways

Dose-response modeling

At what dose do effects occur?

- Identify similarities in gene expression (mode of action across chemicals)
- Compare chemical potency (Dose-response)
- Compare human exposure levels for risk evaluation (where applicable)

Objectives and Approach

- **Overarching:** Use gene expression profiling to acquire information on PFAS to for application toward human health risk assessment
 - Conduct a high-throughput transcriptomic dose-response and time series analysis of primary human liver spheroids exposed to PFAS
- Experiment 1 - Microscopy
 - Microscopic characterization of biochemical responses of spheroids to PFAS (staining for markers of toxicity)
- Experiment 2 - Time-series, dose-response analysis of prototype PFAS
 - Cytotoxicity assessment and Tempo-Seq analysis
 - Development of bioinformatics pipeline
- Experiment 3 - Prioritize PFAS and mixtures; time- and dose-response
 - Establish potency ranking within the class of PFAS

Overview

Model

In vitro model to predict human responses

Approach

Dose-response and time series

Output

Resultant data
(cytotoxicity, gene expression, benchmark dose)

Application

chemical similarities and potency comparisons

Confirming the model

Model

In vitro model to predict human responses

Primary human cell spheroids:

- Spheroid hepatocytes and Kupffer cells
- Pooled samples from 10 donors
- Toxicological model representation of liver tissue

Microscopy images of primary human liver spheroids

(100x magnification) • Cyclosporin A (CsA) – known inducer of steatosis

Objectives and Approach

- **Overarching:** Use gene expression profiling to acquire information on PFAS to facilitate read-across for human health risk assessment
 - Conduct a high-throughput transcriptomic dose-response and time series analysis of primary human liver spheroids exposed to PFAS
- Experiment 1 - Microscopy
 - Microscopic characterization of biochemical responses of spheroids to PFAS (staining for markers of toxicity)
- Experiment 2 - Time-series, dose-response analysis of prototype PFAS
 - Cytotoxicity assessment and Tempo-Seq analysis
 - Development of bioinformatics pipeline
- Experiment 3 - Prioritize PFAS and mixtures; time- and dose-response
 - Establish potency ranking within the class of PFAS

Experimental design

Approach

Overview of experimental design

Exposure

- 4 PFAS (replicates = 4)
- Dose range (0 to 100 μM)
- Time series (1, 4, 10 and 14 days)

Assessment

1. Cytotoxicity
2. Genomic responses
3. Predicting mode of action, and potency

PFBS

PFOS

PFOA

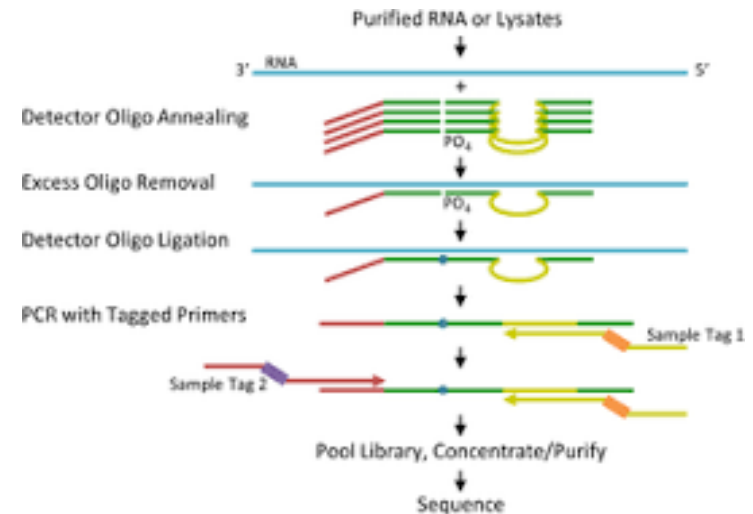

PFDS

High-throughput transcriptomics

Approach

Data generation and handling

- TempO-seq platform (Biospyder) library generation for sequencing from lysates
 - **S1500** gene panel (3000 genes)
- DNA sequencing to quantify the abundance of sister probes that target RNA molecules of interest
- Production of gene expression data

Bioinformatics pipeline development

Approach

Data generation and handling

Raw Data → Gene expression profiles
(Control QA/QC metrics)

Remove outliers

Data visualization (SAV)²
Illumina sequence analysis

Reads extracted from the bcl files from the sequencer (with bcl2fastq v. 2.20.0.42)
→ Fastq files are processed with the “pete.star.script_v3.0” (supplied by Biospyder)
→ Script uses star v.2.5 to align the reads and the qCount function from QuasR

illumina®

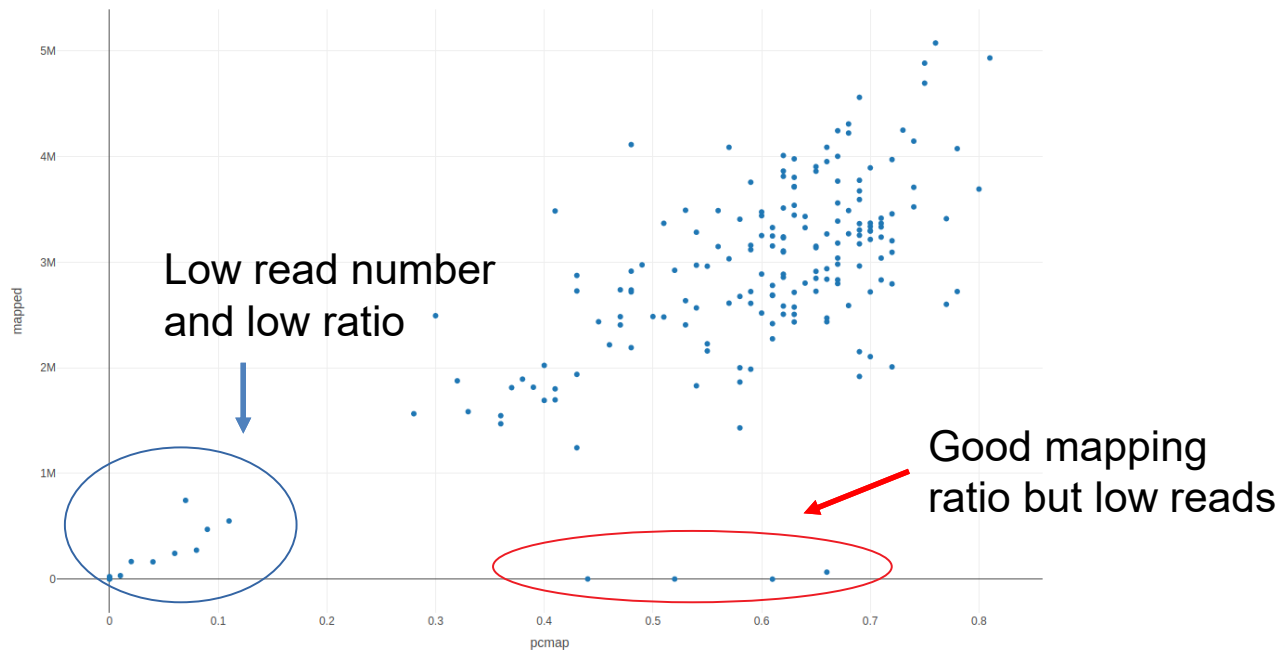

Examine sample coverage and mapping

Approach

Data generation and handling

Total mapped reads versus the percentage of mapped reads for each sample

Probe distribution among each sample

Approach

Data generation and handling

Probe measure (log2 CPM) distributions for a subset of samples.

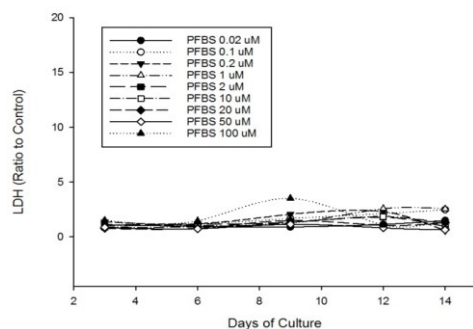

Specific PFAS induce cytotoxicity at higher exposures

Output

Cytotoxicity over 14-Day exposure
(Lactate dehydrogenase assay - LDH)

PFBS

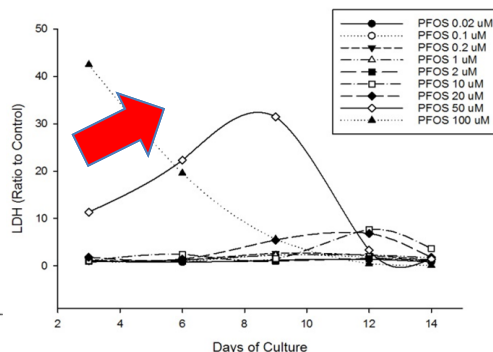

LDH Release by Human Liver Spheroids

- No observed cytotoxicity

PFOS

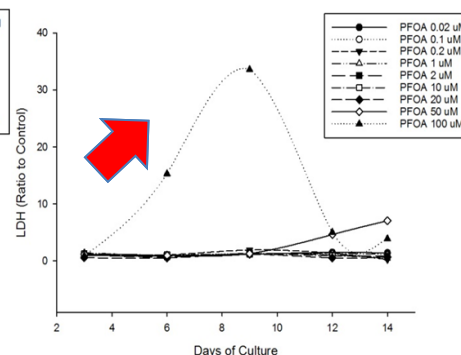

LDH Release by Human Liver Spheroids

- 100 µM cytotoxic (Day 8 – cell death)
- 50 µM steadily ↑ cell death

PFOA

LDH Release by Human Liver Spheroids

- 100µM ↑ Cytotoxicity until Day 8
- 50µM ↑ Cytotoxicity after Day 8

PFDS

LDH Release by Human Liver Spheroids

- ↑ Cytotoxicity 50 & 100 µM (Day 8/10)
- ↑ Cytotoxicity at 2, 10, and 20 µM (Day 10/12)

Increasing number of expressed genes with exposure

Output

Differentially Expressed Genes (DEGs)

1-Day

Gene expression

Exposure vs. Control (DMSO)

- 1.5-fold change
- p-value < 0.05 (FDR adjusted)

Expected patterns

- ↑ DEGS from low to high dose
- Potency: PFOS >> PFBS

X → removed samples (cytotoxicity)

Establishing correlation between expression profiles

Output

Differentially Expressed Genes (DEGs)

Hierarchal Cluster Analysis
(consolidated replicates by concentration at 1-Day exposure)

Clustering of high concentration samples

Highest source of variation with dose

Output

Differentially Expressed Genes (DEGs)

Principal component analysis (PCA)

Correlation with dose

Method to reveal correlations
with experimental conditions

- Group
- Dose

What is a benchmark dose?

Output

Benchmark dose (BMD)

1. 3000 genes (S1500 panel)
2. Subset of genes exhibiting a change in response (William Trend Test)
3. Filtered genes are matched to best-fit models
 - BMD based on BMR

Here, we use 1 standard deviation

Increasing potency of PFAS with exposure time

Output

Benchmark dose (BMD)

Median gene BMDs (95 % confidence interval)

- PFBS – Least potent
- PFOS – Most Potent
- PFOA } Increase potency with time
- PFDS } Equipotent to PFOS by Day 14

Increasing Potency

Accumulation plots an indication of transcriptional activity

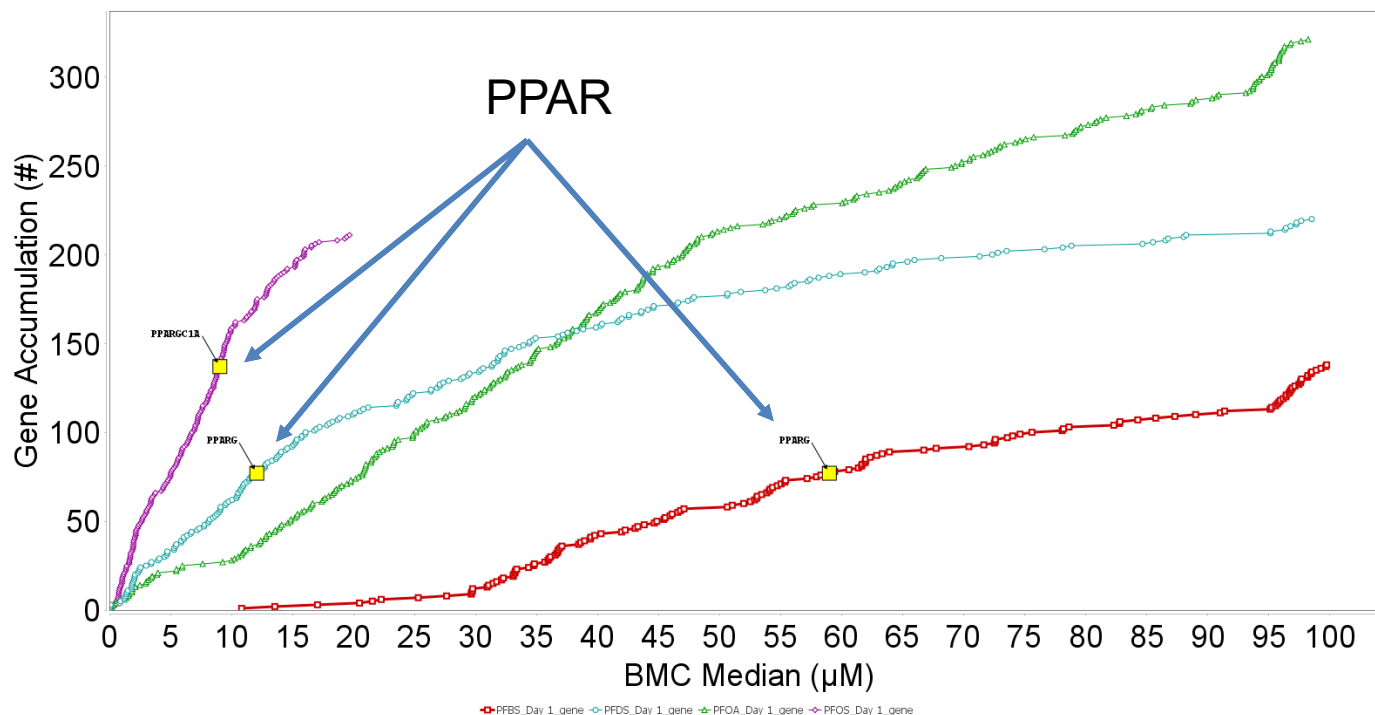

Output

Benchmark dose (BMD)

BMD accumulation plots – gene level

- PFBS
- PFOS
- PFOA
- PFDS

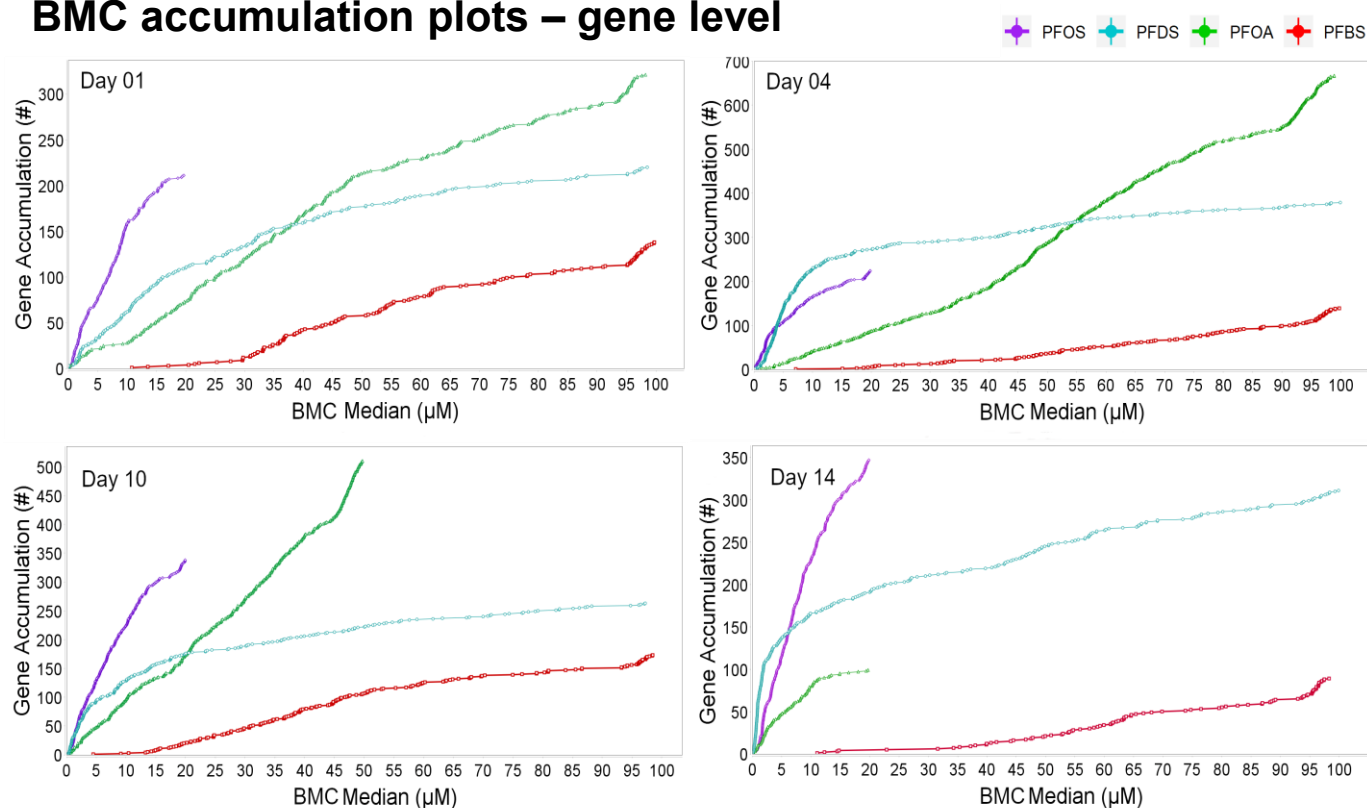

Initiation of transcription activity at low exposures

Output

Benchmark dose (BMD)

BMC accumulation plots – gene level

- Lowest effects occur at similar concentrations for PFOS, PFOA, PFDS (similar potencies)
- Transcriptional activity initiated: 1 – 15 μM

Relevance of exposure in humans

Application

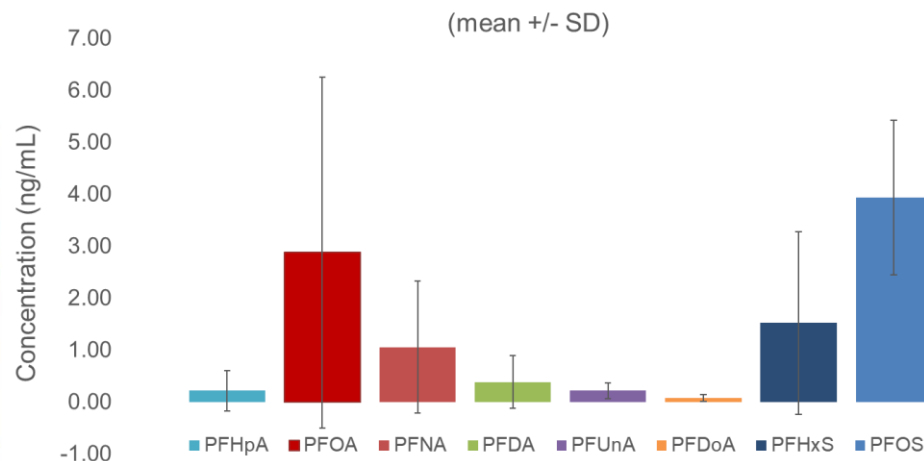

Toxicological relevance

- **Risk:** The likelihood that harm from a specific hazard will occur

(<https://toxedfoundation.org/hazard-vs-risk/>)

$$\text{RISK} = \text{HAZARD} \times \text{EXPOSURE}$$

Levels of PFAS in human blood (ng/mL)
(Reardon *et al.* 2019)

Determining the level of risk

Application

Bioactivity Exposure Ratio (BER)

Transcriptional
BMD value
(μM)

Conversion
factor*

Administered
equivalent dose
(mg/kg-BW/day)

Bioactivity-exposure
ratio

Upper limit of the daily
population exposure

(<https://comptox.epa.gov/dashboard>)

*The reverse dosimetry approach (Wetmore *et al.*, 2015) for PFOA and PFOS (as described in Wambaugh *et al.* 2013) was used to determine a conversion factor to calculate the administered equivalent dose from the benchmark concentration estimate of *in vitro* models.

PFOS and PFOA pose risk at current exposure levels

Application

Bioactivity Exposure Ratio (BER)

BER derived by 2 ways:

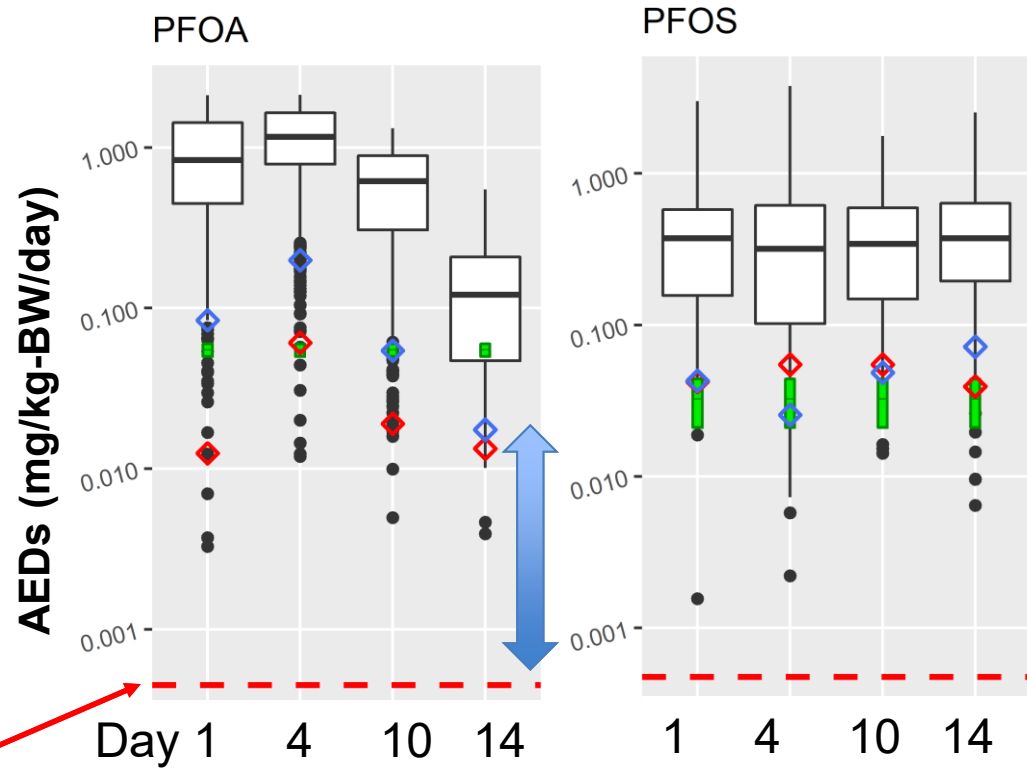

◇ 5th percentile gene

◇ Lowest pathway

- Both approaches were consistent with the apical endpoint BER

■ Animal PoD

- BERs <100, indicating a narrow margin for highly exposed humans levels

Upper limit of daily exposure)
(<https://comptox.epa.gov/dashboard>).

Summary and conclusions

- This study developed a transcriptomic pipeline to distinguish similarities & differences between model PFAS
- The transcriptional BER was highly consistent with the apical endpoint BER in the HC drinking water guidelines → **confidence to this NAM**
 - PFAS exposure → transcriptional changes → BMD modelling for potency
 - PFAS became more potent over time
 - Longer-chain PFAS had similar patterns of potency
 - short-chain PFBS did not follow this pattern
 - Demonstrates the efficiency of high-throughput transcriptomics to provide valuable data to facilitate risk assessment

Rowan-Carroll *et al.* (preprint). High-throughput transcriptomic analysis of human primary hepatocyte spheroids exposed to per- and polyfluoroalkyl substances (PFAS) as a platform for relative potency characterization

Objectives and Approach

- **Overarching:** Use gene expression profiling to acquire information on PFAS to facilitate read-across for human health risk assessment
 - Conduct a high-throughput transcriptomic dose-response and time series analysis of primary human liver spheroids exposed to PFAS
- Experiment 1 - Microscopy
 - Microscopic characterization of biochemical responses of spheroids to PFAS (staining for markers of toxicity)
- Experiment 2 - Time-series, dose-response analysis of prototype PFAS
 - Cytotoxicity assessment and Tempo-Seq analysis
 - Development of bioinformatics pipeline
- Experiment 3 – Prioritizing PFAS as a class; time- and dose-response
 - Establish potency ranking within the class of PFAS

Overview

Model

In vitro model to predict human responses

Approach

Dose-response and time series

Output

Resultant data
(cytotoxicity, gene expression, benchmark dose)

Application

chemical similarities and potency comparisons

Overview

Model

Primary human liver spheroids (Experiment 1)

Approach

**Bioinformatics pipeline (Experiment 2)
Assessment of overall trends in PFAS responses**

Output

Resultant data for a large group of PFAS

Application

Chemical Potency

Scaling up to a larger number of PFAS

Approach

Overview of experimental design

Exposure

- 23 PFAS
- Dose range (0 to 100 μ M)
- Time series (1, and 10)

Data handling

- Use bioinformatics pipeline developed as part of experiment 2

Assessment

1. Cytotoxicity (same approach as from experiment 2)
2. Genomic responses
3. Potency rankings

Scaling up to a larger number of PFAS

Approach

Overview of experimental design

Categorizing PFAS

Perfluoroalkyl carboxylates
(PFCAs)

Perfluorooctanoate
(PFOA)

Perfluoroalkyl sulfonates
(PFSAs)

Perfluorooctane sulfonate
(PFOS)

PFAS precursors

8:2 Fluorotelomer alcohol
(8:2 FTOH)

Longer-chain PFAS increase in DEGs with exposure

Output

Differentially expressed genes (DEGs)

- Shorter-chain PFAS do not show trend in DEGs
- Longer-chain PFAS increased DEGs with exposure conc.

BMD accumulation plots – gene level

1-Day Exposure

10-Day Exposure

PFCAs

PFAS precursors have no discernable trend

Output

Benchmark Dose

1-Day Exposure

- PFOSA (a PFOS precursor) was found to exhibit the highest potency and transcriptional activity of this subgroup

Experiment 3 - Summary

- Relationships between chain length & extent of transcriptional alterations, and potency that emerged that can be used to inform read-across
- PFAS cause cytotoxicity in human liver cell spheroids & transcriptional changes at similar concentrations to PFOS and PFOA, suggesting these chemicals are harmful to human liver
- This case study is building confidence in the application of transcriptomic BMD modelling for:
 - Potency comparisons
 - Chemical prioritization, scoping/screening assessments

Reardon *et al.* (preprint). High-throughput transcriptomics and benchmark concentration modeling for potency ranking of per- and polyfluoroalkyl substances (PFAS) in exposed human liver cell spheroids
